Introduction

- A flexible storage model
 - B+ Tree

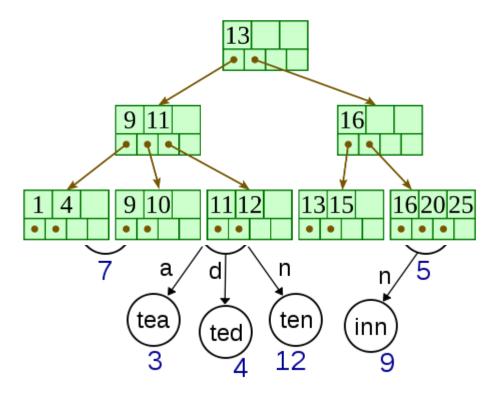

B+tree have excellent performance in managing disk IO and high cache utilization capabilities.

But they require more effort for multi-threaded concurrency, which can also lead to increased management difficulty.

- A flexible storage model
 - Masstree --- Attempt to inherit the advantages of B+tree while optimizing its drawbacks

Masstree is composed of multiple B+trees to form a trie.

- A flexible storage model
 - Masstree --- Attempt to inherit the advantages of B+tree while optimizing its drawbacks

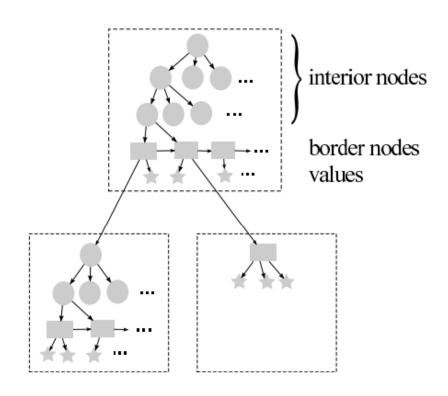

Layout considering cache efficiency

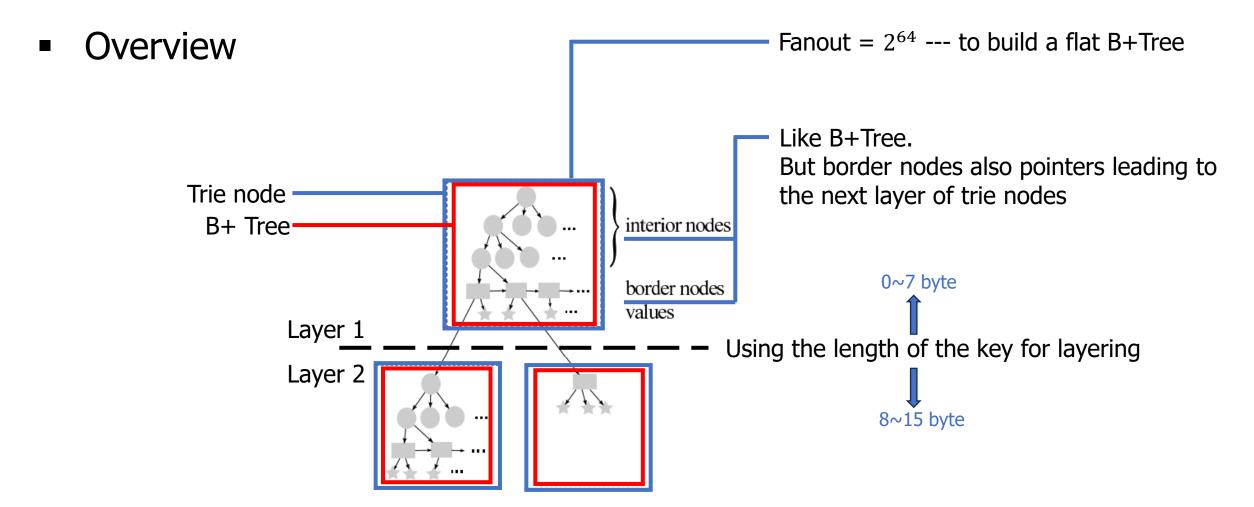

Non-cache-polluting lookup

Concurrent non-blocking lookup

Non-blocking insert

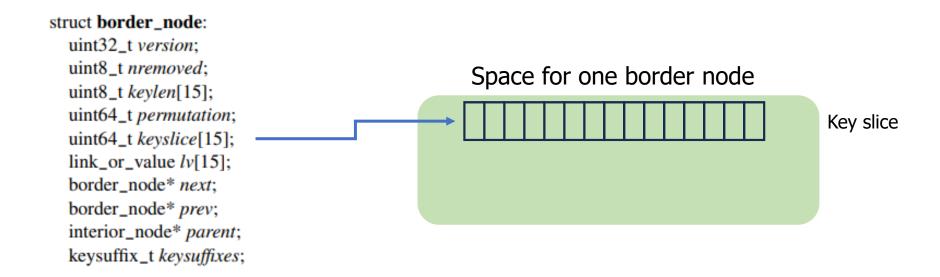

Persistent

This construction can achieve that all keys contained in the leaf node of trie have the same prefix

Layout

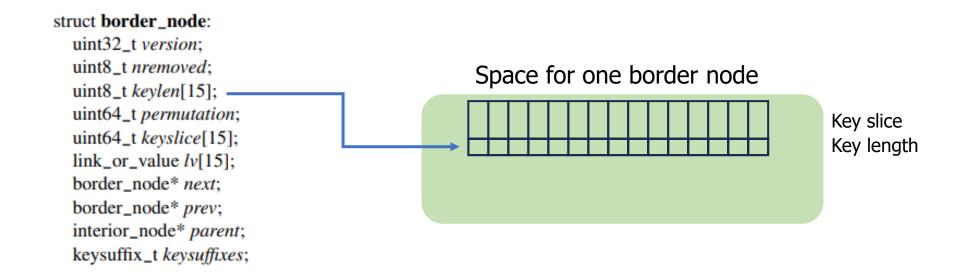

15 key slices (prefixes) with a length of 8 bytes form a border node

Layout

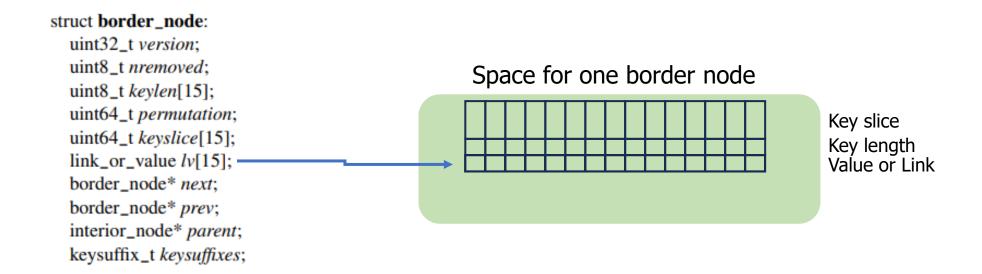

The total length of 15 1-byte array record keys

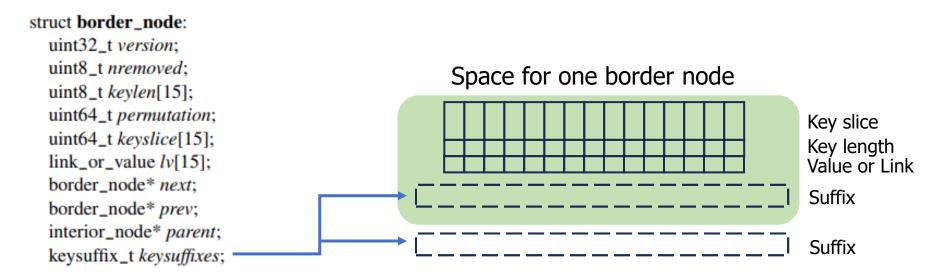

Layout

A list consisting of 15 elements is used to record whether the corresponding ke y slice is an accurate key or a point to the next layer.

Layout

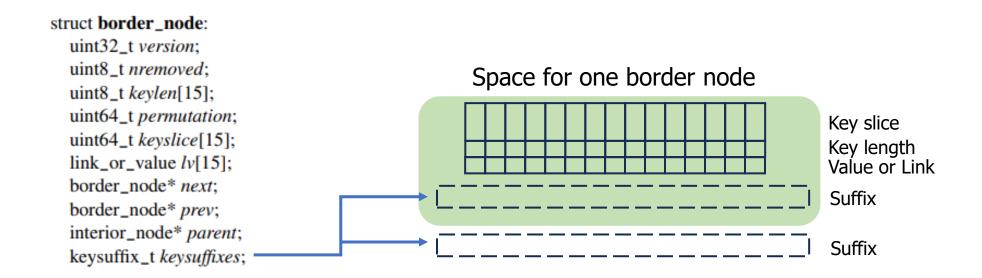

When the length of a key exceeds the processing length of this layer, but there are not enough keys with the same prefix to construct the next layer's node, it is responsible for storing the excess processing length.

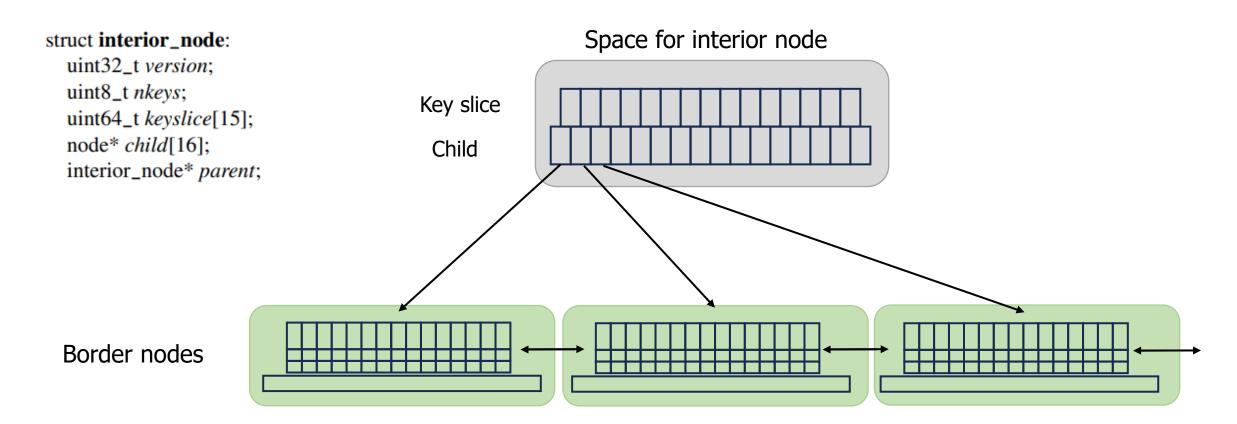

Layout

The size and storage location of keysuffixes will be selected to be stored in the border node structure or in an independent memory space according to the situation.

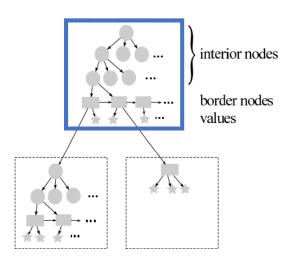

Layout

- Layout
 - Put a key as "01234567AB"

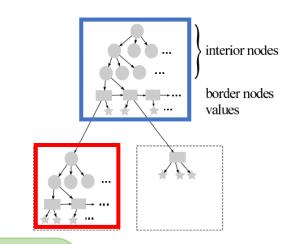

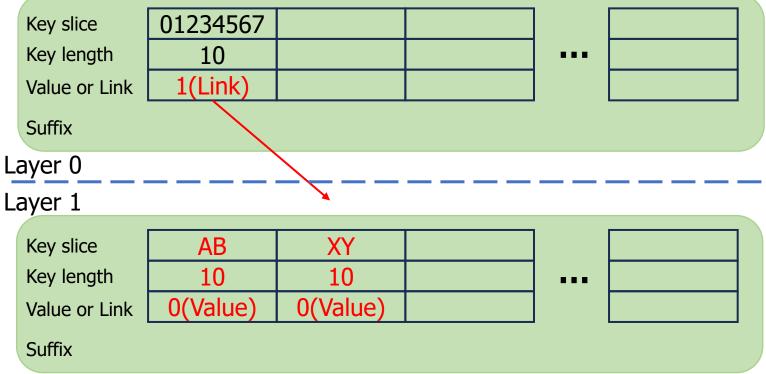

Key slice	01234567			
Key length	10			
Value or Link	0(value)			
Suffix	AB			

Border node in trie's root node

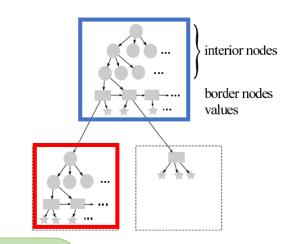

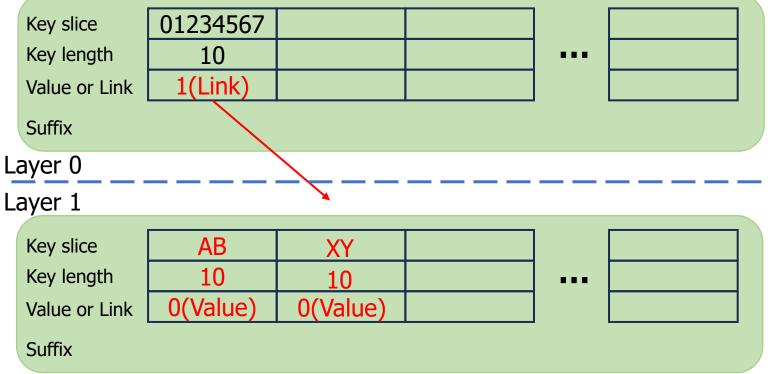

- Layout
 - Put a key as "01234567XY"

- Layout
 - Remove a key as "01234567XY"

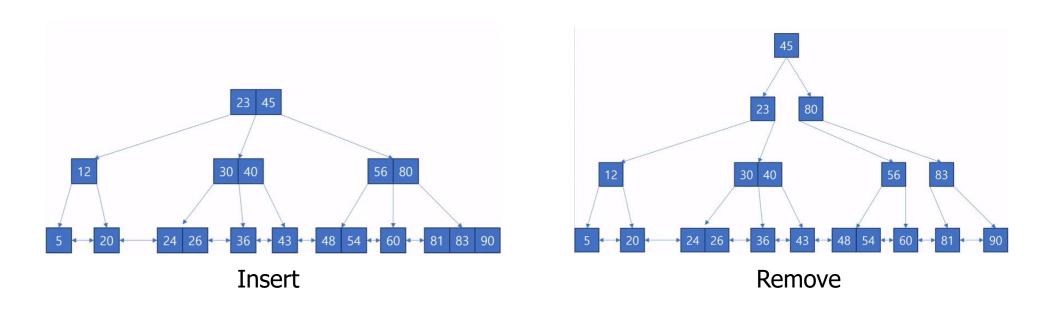

- Layout
 - Other things
 - Masstree must be able to distinguish between 8-byte key "0123456□n" and 7-byte key "0123456" with empty characters.
 - When there are too many keys with the same prefix, Masstree allows for the construction of up to 10 keys with the same prefix within the node layer above the stored key
 - The key suffix data structure will be stored inside or outside the trie node depending on the situation, and its size is variable.
 - About uint64_t keyslice[15]:
 Conduce to L3 cache to read an entire node at once.

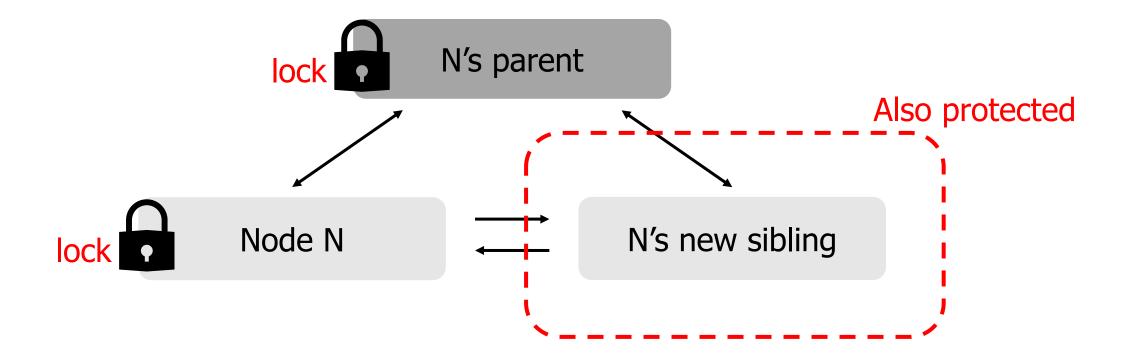

Nonconcurrent modification

The B+Tree constructed by Masstree also has issues such as node splitting during insert and remove operations, and provides solutions accordingly

- Writer-Writer coordination
 - Splits and node deletions require a writer to hold several locks simultaneously

Writer-Reader coordination

Use *version*

- Writer-Reader coordination
 - update

- Update operation must prevent concurrent readers from observing intermediate result
- Read-copy update technology → Collect and process at once

- Writer-Reader coordination
 - Border insert

uint64_t *permutation*

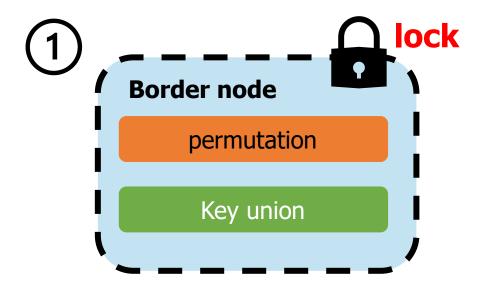

- nkey: Current number of key
- keyindex: Correct key order → store the indexes of the border node's live keys

Unlive key

→ List currently-unused slots

- Writer-Reader coordination
 - Border insert

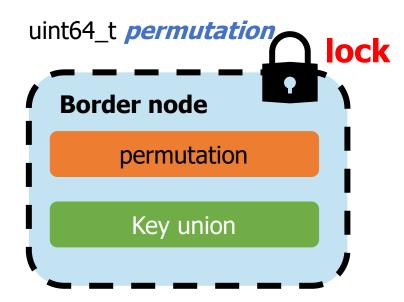

- Writer-Reader coordination
 - Border insert

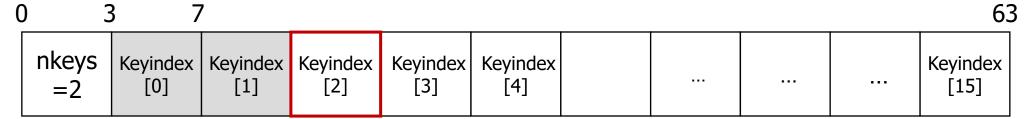

2 Load the permutation

() 3	3	<i>,</i>						6.	3
	nkey =2	Keyindex [0]	Keyindex [1]	Keyindex [2]	Keyindex [3]	Keyindex [4]		 	Keyindex [15]	

- Writer-Reader coordination
 - Border insert

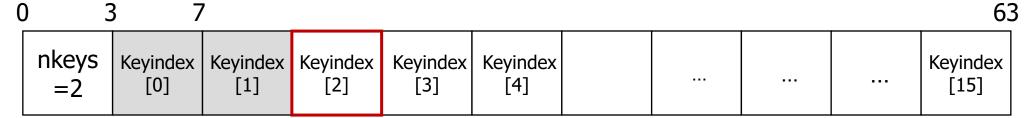

uint64_t *permutation*

position of the key to be inserted

- (3)
- Rearranges the permutation to shift an unused slot to the correct insertion position
- increment nkeys

- Writer-Reader coordination
 - Border insert

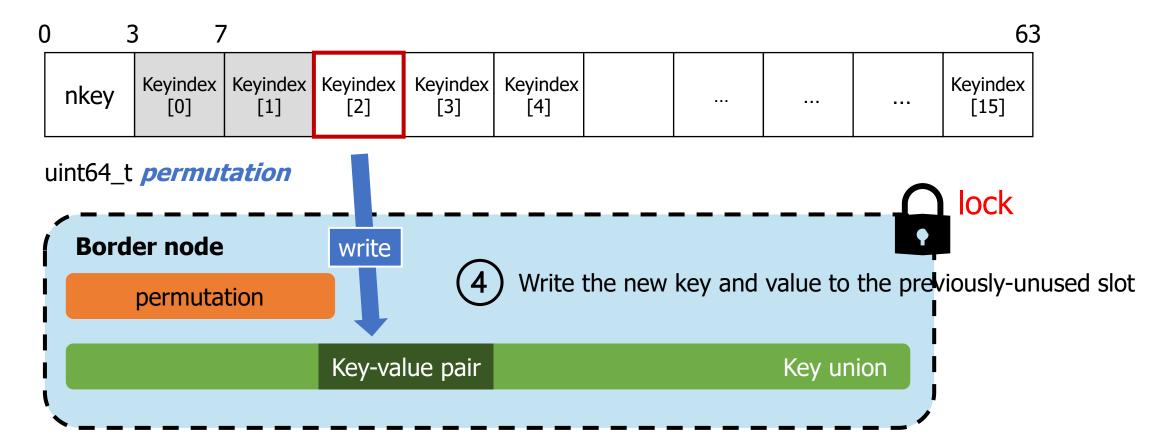

uint64_t *permutation*

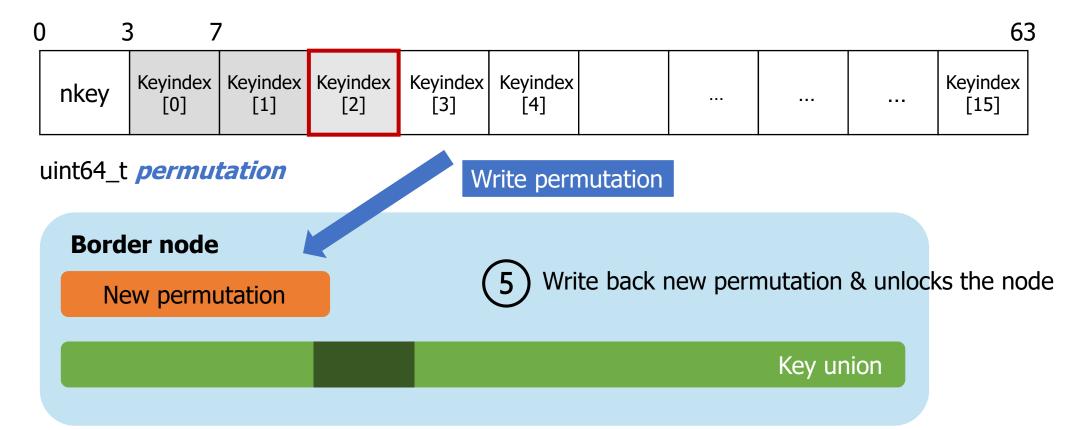

position of the key to be inserted

- (3)
- Rearranges the permutation to shift an unused slot to the correct insertion position
- increment nkeys

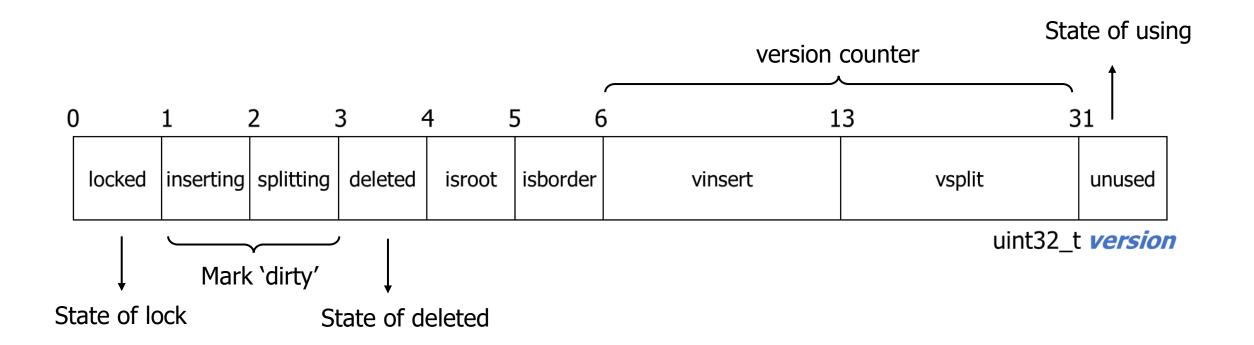

- Writer-Reader coordination
 - Border insert

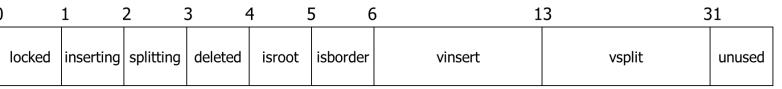

- Writer-Reader coordination
 - Border insert

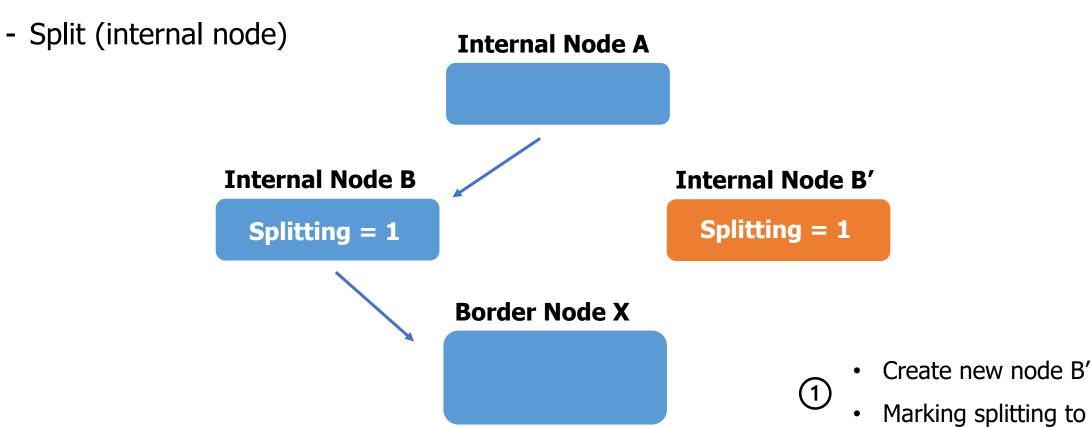

- Writer-Reader coordination
 - Use hand-over-hand locking

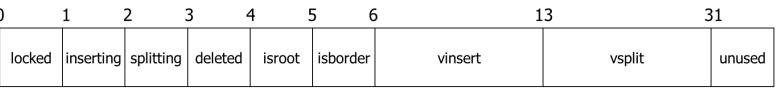

uint32_t version

Writer-Reader coordination

- Marking splitting to B & B'

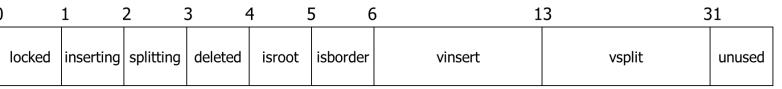

uint32_t *version*

Writer-Reader coordination

- Split (internal node) **Internal Node A Internal Node B Internal Node B' Splitting = 1** Splitting = 1**Border Node X**

2 Children (including X) are shifted from B to B'

uint32_t *version*

Writer-Reader coordination

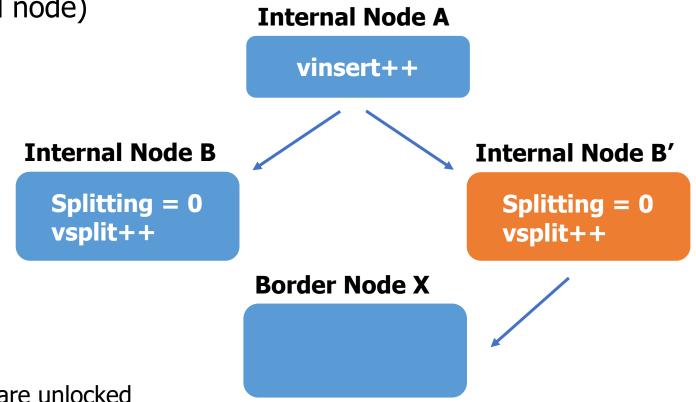

- Split (internal node) **Internal Node A** The new node B' is inserted into A **Internal Node B' Internal Node B Splitting = 1** Splitting = 1**Border Node X**

()	1	2 :	3 4	1 5	5 6	1	3	31
	locked	inserting	splitting	deleted	isroot	isborder	vinsert	vsplit	unused

uint32_t *version*

Writer-Reader coordination

- Split (internal node)

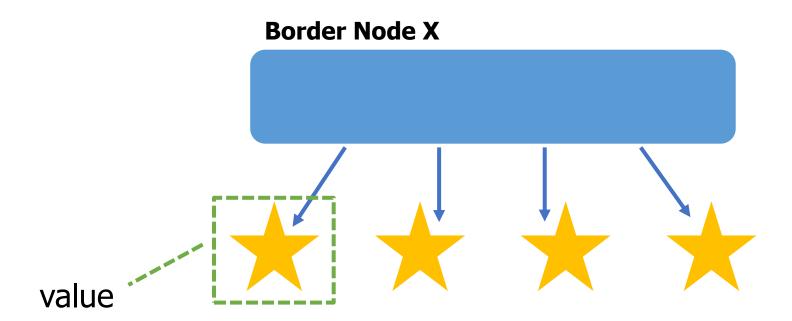

- A,B, and B' are unlocked
- Increments the A vinsert counter and the B and B' vsplit counters

)	1	2 :	3 4	} 5	5 6	1	3	81
locked	inserting	splitting	deleted	isroot	isborder	vinsert	vsplit	unused

uint32_t *version*

- Writer-Reader coordination
 - Split (border node)

)	1	2 :	3 4	} 5	5 6	1	3	81
locked	inserting	splitting	deleted	isroot	isborder	vinsert	vsplit	unused

uint32_t *version*

- Writer-Reader coordination
 - Split (border node)

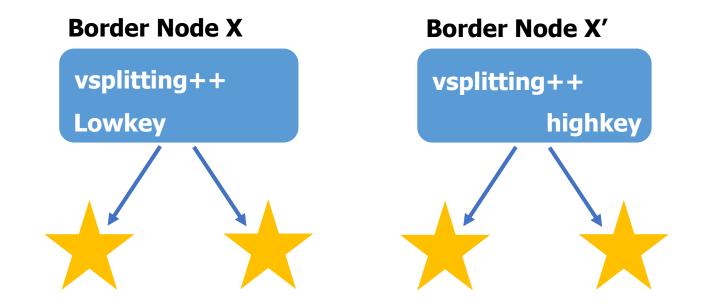

Lowkey highkey

Range of key: [lowkey(n),highkey(n))

)	1	2 :	3 4	} 5	5 6	1	3	81
locked	inserting	splitting	deleted	isroot	isborder	vinsert	vsplit	unused

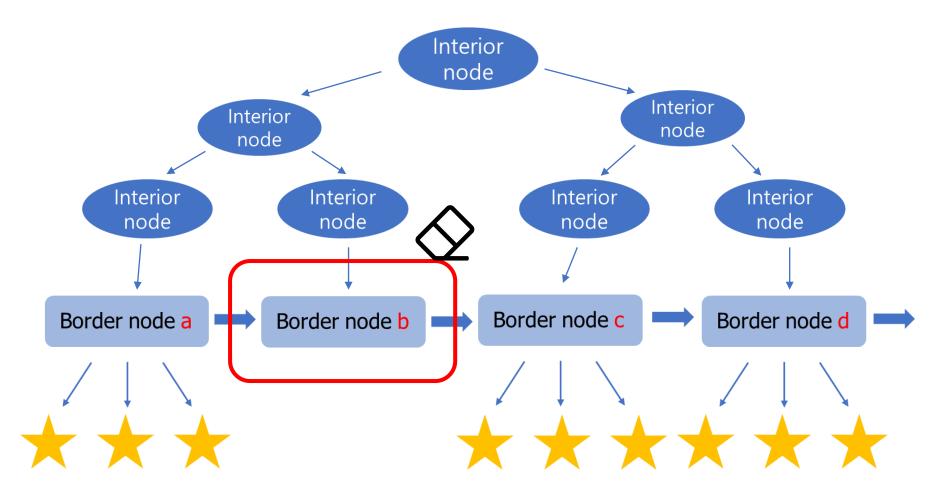

uint32_t *version*

- Writer-Reader coordination
 - Split (border node)

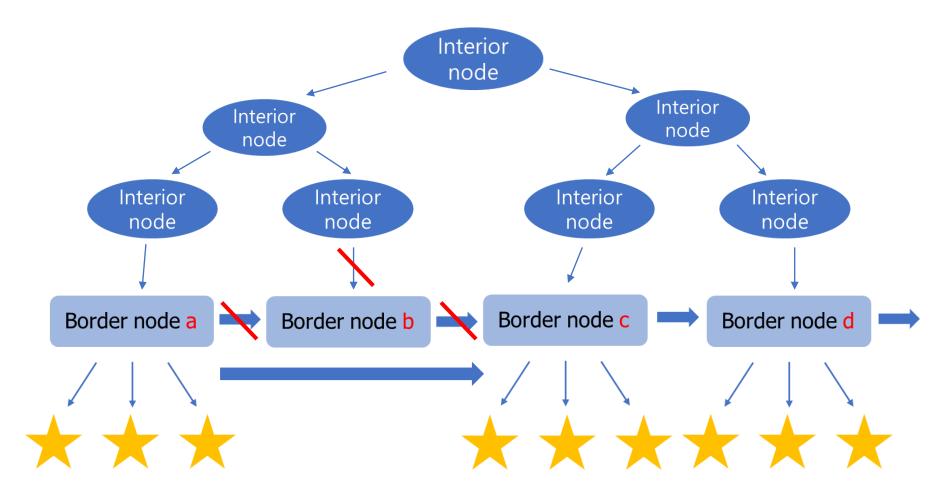

Lowkey(n) remains constant over n's lifetime

Discussion

- More than 30% of the cost of a Masstree lookup is in computation
 - Computation = key search within tree node
 - Linear search has higher complexity than binary search
 - Linear search exhibits better locality

Evaluation

- Two-part Evaluation
 - Masstree as a data structure
 - Compare with other data structures
 - Impact of various design choices and optimizations

- Masstree as a system
 - Compare with other storage systems

Evaluation

Setup

- 6-cores 2.4GHz AMD Opteron 8431 chips X 8 (On test only use 16-cores)
- 8GB DRAM per chip (On test: 24GB DRAM)
- SSD X 4 (write speed: 90 ~ 160 MB/s)
- 10 Gb Ethernet card
- 25 client machines send queries over TCP

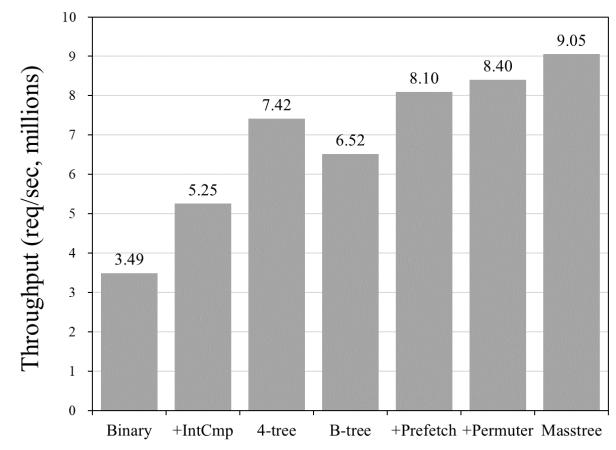

Performance

- Put (w/o log, network clients)
 - 16 cores put workload with 140M-key, 1-to-10-byte decimal

Comparison Group

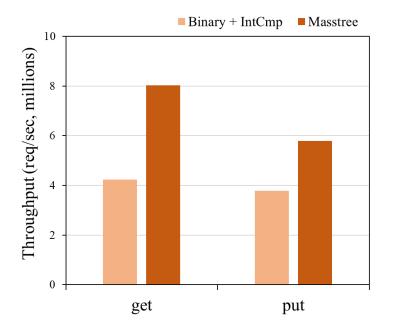

- Binary tree
 - +IntCmp(+Flow, +Superpage)
- 4-tree
- B-tree
 - +Prefetch
 - +Permuter
- Masstree

System relevance

- With logging, network clients
 - 16-cores get and put workload with 140M-key, 1-to-10-byte-decimal

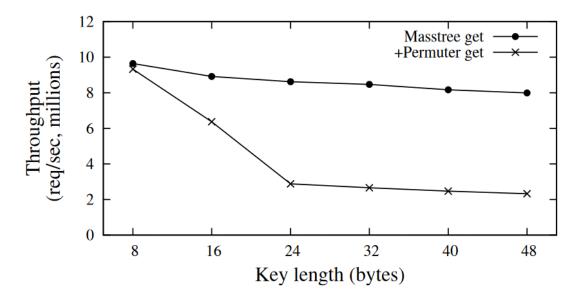

- Masstree outperformed by **1.9x** and **1.53x** for get and put
- → Masstree design can improve system performance

Flexibility

- Keys with common prefixes
 - Keys differ only in the last 8 bytes

- "B-tree+Permuter" incurs a cache miss for the suffix of every key it compares
- Masstree has **3.4**× the throughput for relatively long keys

Flexibility

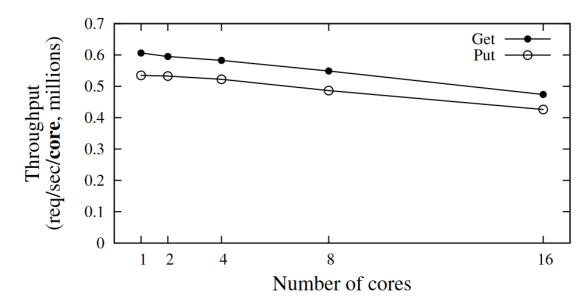

- Variable-length keys
 - Compare with B-tree supporting 8-byte fixed size keys
 - 16-core get workload with 80M-keys, 8-byte decimal
 - Masstree's throughput was only 0.8% behind
 - → Masstree design **effectively has fixed-size keys** in most tree nodes
- Concurrency
 - Compare with single-core version of Masstree
 - 1-core put workload with 140M-keys, 1-to-10-byte-decimal
 - Concurrent Masstree is beaten by single-core Masstree by just 13%
 - → Additional overhead for Concurrent Masstree is **not significant**

Scalability

- Masstree's performance scales with the number of cores
 - 16-cores get and put workload with 140M-key, 1-to-10-byte-decimal
 - Y axis shows per-core throughput

- 16-cores Masstree scales to 12.7× and 12.5× its 1-core performance for gets and puts
- → More cores means more competition between cores for some limited resources

System Evaluation

- Compare Masstree with other systems
 - MongoDB: key-value store using B-tree
 - VoltDB: in-memory RDBMS
 - memcached: in-memory key-value store using hash table
 - Redis: in-memory key-value store using hash table

Server	C/C++ client library	Batched query	Range query
MongoDB-2.0	2.0	No	Yes
VoltDB-2.0	1.3.6.1	Yes	Yes
memcached-1.4.8	1.0.3 latest hiredis	Yes for get	No
Redis-2.4.5		Yes	No

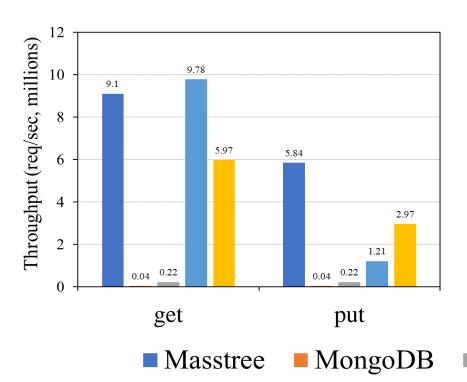

Figure 12. Versions of tested servers and client libraries.

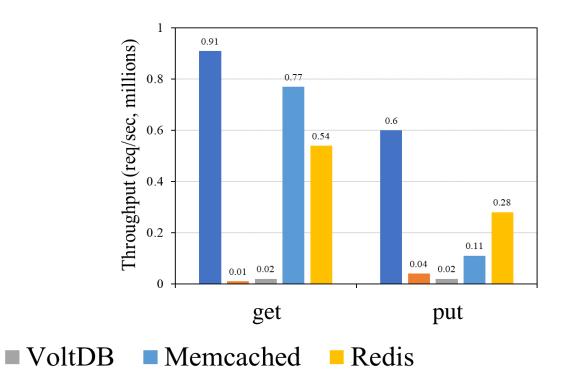

System Evaluation

- Compare Masstree with other systems
 - Uniform key popularity, 20M keys, 1-to-10-byte decimal, one 8-byte column

- 16 cores

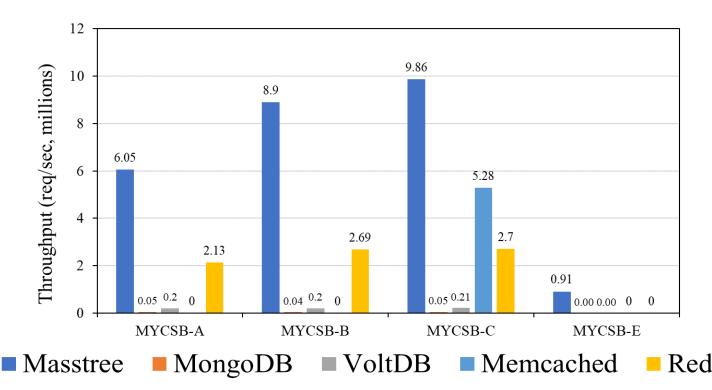

- 1 core

System Evaluation

- Compare Masstree with other systems
 - 16 cores, Zipfian key popularity, 5-to-24-byte keys, ten 4-byte columns for get, one 4-byte column for update & get range

MYCSB-A (50% get, 50% put) MYCSB-B (95% get, 5% put) MYCSB-C (all get) MYCSB-E (95% getrange, 5% put)

Conclusion

- Masstree is persistent in-memory key-value database
 - Consist of a trie-like concatenation of B+-trees
 - Keep all data in a tree, and the tree is shared among all cores
 - Provide consistency and durability by logging and checkpointing

- Masstree executes more than 6M simple queries per second
 - Masstree's performance is comparable to memcached and higher than VoltDB, MongoDB, and Redis

Thank you

Appendix

Masstree

- Layout
 - About time complexity

Essentially, a masstree is a multi-layered B+tree structure.

If the key has l byte, it will be stored in the l /8 layer. In other words, the cost of searching for this key is l /8 times of B+Tree search.

$$O(\log n)$$
The time complexity of a B+Tree. B+Tree with multiple levels. Omitting constants

Considering that the B+tree constructed by masstree always maintains a **flatter structure**, it can be foreseen that if the length of the key is **longer**, masstree will have an **advantage** over B+trees
